In this study we describe a novel method for the covalent grafting of aliphatic poly(ethylene glycol) (PEG) derivatives onto a variety of biomaterials via the formation of esters. This method avoids some of the pitfalls associated with the traditional PEG conjugation methods such as thiolation and esterification. PEG derivatives were prepared by direct esterification of ethylene oxide with the aliphatic polyalcohol poly(ethylene glycol), and linked to amino groups of biomaterials. After deprotection, the PEG derivatives were characterized by water-insoluble proton NMR and FT-IR spectroscopy. The water solubility of surface-modified biomaterials was evaluated by fluorescein (FLU) and poly(ethylene glycol) labeled (PEG-FLU) staining. Surface-modified biomaterials showed excellent water solubility. Although a lower surface coverage was observed on the amino-PEG-modified biomaterial, the changes were not significant. The amino-PEG groups were cleaved by incubation in water for 24h, and the amino-PEG-free groups were prepared for further modification. Models and methods for evaluating the effect of alternative forest management on global forest carbon stocks. Forest carbon is widely recognized as an important component of terrestrial ecosystems. A variety of methods are available for estimating global and regional forest carbon stocks. However, there is growing uncertainty as to which method is most suitable for use in assessing the forest carbon balance. This paper reviews a range of existing methods and models for estimating carbon stocks in forests and identifies the potential advantages and disadvantages of each. It describes criteria for the selection of a model or method, with emphasis on the different types of data required. Finally, it discusses the interpretation and trade-offs between mathematical and empirical models, and the relative merits of estimating carbon stocks at the regional or national scale. 6d1f23a050
